Terminal . writeline ("Hello, World!")

Word dot word bracket open * bracket close

If pattern word dot word open bracket wildcard close bracket

is found then

execute method call state

Replace the call with the value. e.g. Null

first evaluate the wildcard recursively

Terminal . Colour

word dot word

if pattern word dot word is found then

execute attribute access state

Replace the call with their value.

e.g. the terminal colour variable

Logic . if (* ; { * })

word dot word open bracket wild card semi colon open curly wild card close curly close bracket

Must evaluate to boolean, but checking this is handled by the function signature

In the eyes of the function, this is a string array. functions like these logic functions are exceptions, as they can communicate with the aurora interpreter, in order to evaluate their code block.

This falls under the method call state
